Cardiac myocytes appear to originate primarily from a population of progenitor cells located within the perinatal chick heart. The absence of a fetal heart for culturing makes it difficult to obtain large numbers of highly enriched cardiac myocyte-like cells. Thus, a method for the generation of cardiac myocyte-like cells from embryos, which is highly enriched for the desired cell type, would be useful. To this end, we examined the potential of an embryonic chicken heart explant culture system to generate cardiac myocyte-like cells. Heart explants were prepared from chick embryos at stages 30-45 of development. The explants were maintained in culture for 6 days in a chemically defined medium containing basic fibroblast growth factor, heparin, and insulin. The explants were initially composed primarily of connective 520fdb1ae7
