Field of the Invention The present invention generally relates to a system for detecting faults in an internal combustion engine. More specifically, the present invention relates to a system for detecting various types of faults in an internal combustion engine with high precision and reliability by accurately detecting a rotation position of a crankshaft. 2. Background Information A common fault in an internal combustion engine is that the crankshaft is not locked in a rotation position corresponding to a desired engine speed when starting. Due to this fault, the crankshaft starts to rotate earlier than expected, which causes shock or vibration, thereby making a driver or a passenger uncomfortable. In view of this problem, a technique is known for determining whether the engine is being started or whether the crankshaft is locked. For example, Japanese Laid-Open Patent Publication No. 2005-301971 discloses a technique for determining whether the engine is being started or whether the crankshaft is locked by detecting a torque variation in a direction in which the crankshaft is forcibly rotated in a state in which the engine is stopped and by determining that the crankshaft is locked if the detected torque variation is larger than a specified level. In the above technique, a rotation position of the crankshaft is detected by a sensor, such as an encoder, a resolver, or an absolute position encoder, in order to detect the torque variation. However, the crankshaft needs to be rotated from a stop position to a desired rotation position in order to accurately detect the rotation position of the crankshaft with this technique. Therefore, time is needed to accurately detect the rotation position of the crankshaft by this technique. In view of the above problem, a technique is known for precisely detecting the rotation position of the crankshaft by detecting the rotation position of a camshaft that is directly connected to the crankshaft and by detecting the position of a cam that directly rotates the 520fdb1ae7
