AA nurse.plus

The healthcare provider is caring for a patient who has septic shock. Which of these should the healthcare provider administer to the patient first?

IV fluids to increase intravascular volume. ✓

Corticosteroids to reduce inflammation. ✗

Circulation and perfusion are addressed first so IV fluids will be started immediately. After blood cultures are obtained, broad-spectrum antibiotics should be administered without delay. Vasopressors are administered if the patient is not responding to the fluid challenge. Corticosteroids may be considered to address the inflammatory-induced vasodilation and capillary leakage.
