How often do blobfish eat

Blobfish. You may have heard of it or not. This is, after all, extremely rare. If you have one, it's probably because it was chosen as the ugliest animal in the world in 2013, defeating other bizarre creatures such as axolotl, naked mole rat, purple frog and monkey trumpet. Why is it considered so ugly? And what else is there for this mysterious, miserable appearance of creation? Is it a freak of nature or a natural wonder? Let's find out. To comment on this video - visit youtube. 1. Is blobfish real? The first time you hear the word blobfish, you can doubt if it's real. After all, who calls the fish a blob? It sounds like a bad joke, doesn't it? Then again, dumbo octopus, vampire squid, chicken turtle and Christmas tree worm are real, which simply shows that you should not judge an animal by its strange name - or that it is not always easy for scientists to come up with a unique name for the animal. Yes, blobfish is real. It may look like something out of a fantasy movie or horror movie, but it's a real fish. Its scientific name is *Psychrolutes marcidus*, which means it belongs to a family of fish known as fatheads – you could say ugliness is in the blood of blobfish. Little is known about the *Psychrolutidae* family, except that they have large heads, live at the bottom of the ocean and that their name comes from the Greek word *psychrolouteo*, which means to have a cold bath. After all, they like to live where the water is cold. Blobfish, in particular, live at depths of up to 3,900 feet (1,189 meters), where normal pressure is about 118 times higher than sea level. It can be found off the coast of mainland Australia, Tasmania and New Zealand. 2. History behind blob Let's take a closer look at the transformation of blobfish.2. The story behind the blob Let's closer look at the blobfish's transformation. Why is this changing so drastically? This is because the blobfish has no skeleton and no real muscles. It simply consists of a gelatinous substance. Why should this be the case? It's one of the blobfish adaptations. You see, most fish have an organ called a swimming bladder that allows them to swim and swim. Such an air-filled organ, however, would collapse under extreme pressure, blowing the fish to pieces. So instead of a suicidal bath bladder, the blobfish consists of the gelatin of the body. This body is less dense than water, so the blobfish naturally floats above the bottom of the ocean. Indeed, blobfish do not need to spend any energy to swim, which is good and good, because the food is not exactly abundant on the dark bottom of the ocean. 3. Blobfish – The Ugliest in the World Why is Blobfish Considered Ugly? As the U.S. National Oceanic and Atmospheric Administration (NOAA) put it, blobfish looks like a big, blobby tadpole, just a mass of pale, gelatinic puss with puffy, loose skin, a big nose and beady, looking He was also compared to a character from Ziggy's comic book, but with his mouth permanently falling on the corners. Indeed, one look at the blobfish and you'll know why it's so named – it looks like a pile of pink blob, unlike other creatures, in the ocean or above it. 4. ... or not? *Psychrolutes phrictus* by NOAA-MBARI Blobfish, however, only looks like a blob when it is out of water. It has not been photographed in water (because it lives in such deep waters), but scientists believe it looks just like its cousin, blob sculpin (*Psychrolutes phrictus*) with a large head, tapered body, flat tail and spikes instead of scales. The reason why it changes so drastically in appearance is the change in pressure. With water, the air pressure drops exponentially, and so the blobfish is reduced to ... well, blob. In contrast, people, too, will be reduced to spots (or worse) after succumbing to the high pressure that blobfish is accustomed to. Then we would be the ugliest creatures on earth. 5. Does blobfish bite? Blobfish have no bones and therefore no teeth. Even if it can bite, it would turn into a blob before we even had a chance to bite a human – we didn't survive the changes in water pressure very well and we humans would be crushed long before we got to the depths of blobbies to live. 6. What do blobfish eat? No one has ever seen a blobfish eat. However, scientists believe it feeds on crabs, seamsters, sea pens and crustaceans. How do you blobfish them? Since there is no muscle, the blobfish can't hunt, so it just opens its mouth and sucks whatever drifts. Yes, blobfish is one lazy animal, but you too would live in cold, dark and extreme water pressure. 7. Is it possible to eat blobfish? *Psychrolutes phrictus* by NOAA The irony lies in the fact that while blobfish are often caught in the webs of the codek, they never make it to the plate. The moment the blobfish reaches the surface, it turns into a stain and dies, becoming not only bland, but completely inedible. Let's face it. Who would like to eat a stain? 8. Reproduction of Blobfish Like blobfish mate remains a mystery, as do most things about them. It is only known that the female lays thousands of tiny pink eggs on the bottom of the ocean, and she or her colleague guard the eggs, sitting on them until they hatch. This is the most effective way for them to ensure the survival of the young, because there are no plants around to provide shelter for eggs, or any caves where they can make a nest. 9. Is blobfish at risk? Blob fish by Claf Hong cc2.0 Unfortunately, blobfish are currently endangered. In fact, they are close to extinction. Although they are not hunted, blobfish are often caught in the bottom trawling net. These nets pass through the ocean floor, collecting lobsters and other deep-sea fish. Unfortunately, blobfish gets scraped as well, and although it is often thrown back into the ocean, by then it is too late. In 2006, conservationists from around the world came together to propose limiting bottom fishing on the high seas, but were unable to reach an agreement, leaving the fate of helpless blobfish far uncertain, especially as Australia's deep-trawled fishing fleets of Australia and New Zealand are very active and blobfish are nowhere else in the world. 10. Can you keep blobfish as a pet? Keeping blobfish in the tank may seem like a good way to amuse yourself and your friends, but that's one crazy idea you should forget. No blobfish has ever been caught alive, and even if they were, you would need a tank with very high water pressure to keep it alive. You'd be more fortunate to be still, dipping it into alcohol (like the one on display at the Australian Museum), that is, if you want to look at an unhappy creature every day. Blobfish are featured in the following books: 25 Deep Sea Creatures 25 Weirdest Animals Want to Know More? Blobfish isn't that ugly at home – Smithsonian blob fish live deep underwater in a high pressure environment – it's not usually that blobby. Blobfish is facing extinction - the Telegraph Thanks to deep-sea blobfish trawlers - officially the ugliest animal in the world - it may be facing extinction. The ugliest animal in the world – it's official! - BBC News Finally - the recognition it deserves. Is it really that ugly? Really? - Science News How hideously ugly is it? Sources: t-as-ugly-as-you-think-it-is-6676336/?no-ist /www.citellighter.com/animals/animals/knowledgecards/blobfish-psychrolutes-marcidus Photo: Smithsonian Magazine In the Water World, There are many stunning looking creatures such as tangerines, rainbow parrots and clownfish. If they are Cinderellas There are many ugly stepsisters to choose from. But no one has a reputation for being as ugly as blobfish. Its appearance is difficult to understand by the description itself, but it almost looks as if someone made a form of gelatin of the old man's head and left it in the sun, where he slowly began to melt. His ugly appearance led to him being considered the ugliest animal in the world. While some find blobfish hideous, there are those who think it's so ugly that it's cute. Either way, he has gained a lot of attention to his appearance, so let's take a closer look at this sea creature. Looks different Underwater photo via Reddit Remember that gelatinated look the type we mentioned? Blobfish just looks that way over the water. In a normal environment that is underwater from 2,000 to 4,000 feet, the pressure makes it look like any ordinary fish. But as it is brought to the surface, caught in the fishermen's fishing nets, the water pressure decreases and the blobfish begins to lose its shape. This is not the type of fish fishermen are looking for, so some are trying to throw them back as an attempt to save their lives. It is not known if it works and whether they can survive long enough to return to depth after losing so much water pressure. But it seems unlikely, given their distorted appearance when they reach the surface. They don't have bones or a lot of muscle mass their bodies don't really need bones because crushing depth pressure give them all the support they need. I don't need a lot of muscle either. For survival, the blobfish basically hangs just above the bottom of the ocean, moving your mouth to catch food. His diet consists mainly of molluscs and crabs that cross his path. We don't know everything about them because they live so deep in the water, we haven't been able to learn too much about them. Their vitality and reproductive habits are unknown to us. Although we don't know much about their current numbers, some scientists fear that they are in danger of extinction. We don't know all the places where blobfish can live - we chalk that up as another of the mysteries of the deep, but we know for sure that they are located near Tasmania, Australia and New Zealand. They ride on the wave of popularity Being this ugly has its own atuli. Blobfish has become one of the most recognizable deep-sea creatures out there. It can be found on t-shirts, memes and even in songs. We are their biggest threat Photo Credit: Wonderopolis That deep underwater, blobfish are safe from predators – at least as far as we know. Most of the threat to their population comes from humans. And although many of them die as a result of the vets, we do not eat. This is partly due to the texture of the fish when it is located, but also because the blobfish have a lot of taste. We don't know all the places where blobfish can live - we chalk that up as another of the mysteries of the deep, but we know for sure that they are located near Tasmania, Australia and New Zealand. Who knows where else they can be? This is just one of the enticing mysteries of this amazing creature. For more interesting facts about marine life, follow us on YouTube, Facebook & Instagram.
