CrackZone 7 is now available for free in the CrackZone Serials Page.Schizophrenia is a devastating disorder characterized by positive symptoms (delusions and hallucinations), negative symptoms (blunted affect, avolition and anhedonia), and cognitive impairment. Antipsychotics are currently the most effective treatments for positive symptoms, but many patients are poorly responsive and/or have side effects that limit their effectiveness and quality of life. Emerging treatments for negative symptoms include repetitive transcranial magnetic stimulation (rTMS) and deep brain stimulation (DBS), which provide symptomatic benefits in some patients, but their overall efficacy remains unproven. Thus, a better understanding of the neural systems that underlie positive and negative symptoms of schizophrenia is needed to enhance the development of new therapeutics. Human studies have established that disruption of the temporo-parietal junction (TPJ) is associated with delusions and hallucinations in patients with schizophrenia, while functional neuroimaging and postmortem studies in patients and non-human primates indicate that the TPJ is critical for the generation of an appropriate context-dependent behavioral response. The overall goal of this project is to examine the relationship between normal and abnormal function of the TPJ and its role in the pathophysiology of schizophrenia by utilizing a set of innovative techniques that can directly examine neural activity and connectivity in humans. Our first aim is to determine the functional neuroanatomy of the right TPJ by using functional magnetic resonance imaging (fMRI) in conjunction with two different paradigms, one to activate the TPJ and one to inhibit it. By comparing activity in patients with schizophrenia to normal control subjects, we will be able to determine whether functional abnormalities within the right TPJ are associated with positive symptoms, negative symptoms, cognitive impairment, or a combination of these factors. Our second aim is to examine the topographic organization of the right TPJ by using phase-based fMRI, which enables us to measure changes in the amplitude of the f 520fdb1ae7
