exe,.dll, and.zip files are not allowed (unless the platform mandates the use of those file formats). Using the QP/MQTT-based applications available from [www.mongodb.com](you can quickly and easily set up a location for you to back up your data. These applications will facilitate the "building up" of a [MongoDB](#whatis){ref-type="other"} deployment over several weeks

or months, but they will not provide the full level of backup or restore provided by [VMware](#whatis){ref-type="other"}. VMware has supported the QP/MQTT specification since version 1.3.0 of the product. This means that any program written to connect to the mongoDB and mqtt provider will function with VMware. If you wish to use a third party tool, for example to provide a remote vault to store the data, please use the MongoDB manual instructions for doing so. These instructions are for the VMware ESX Server product only. The following section describes the implementation of this feature. Introduction {#Sec1} ============= In addition to the MQTT (message broker) application, it is also necessary to be able to store the data, for example to provide a vault for backing up the data. These instructions describe how to set up a vault using VMware. VMware contains three physical components: the storage area network (SAN) component, the host system and the virtual machine (VM). It is assumed that the data that is stored in the vault can be replicated using a second system. The structure of the system is defined by the network components used in the storage array, the number and type of hosts and VMs that are needed to be provisioned, and the host operating system and the VMware tools that are used to create the VMs. The network components of VMware that are required to be described here include: *The VMware Storage Array* VMWARE requires that the data is stored on a SAN, either local area network (LAN) or wide area network (WAN). The details of the SAN requirements can be found at 520fdb1ae7
