## Vista 40 programming

You've been running Windows Vista, you've been playing with an aerointerface, and you might have even pulled around a little bit in the guts of Vista to see what makes it tick. What now? Now it's when the fun starts. There are many ways you can hack Windows Vista, make it jump through hoops, bend it at your will and generally make it behave the way you want it to behave, not the way Microsoft does. Also do not miss the ultimate tweaker guide for Windows. Where to start? I have put together 10 of my favorite hacks in Windows Vista. They let you do everything from speeding up Windows Aero to unlocking a supersecret administrator account and juice up right-click on the context menu - and yes, even hack the dreaded User Account Control. So if you want to take control of Windows Vista, read on. Warning: Some of these tips include editing the Windows registry, which can be a dangerous thing to do. So before you touch the registry, use System Restore to create a restore point so that you can return to the previous version of the registry if something goes wrong. To create a restore point, click Control Panel > System and Maintenance > Restore files from backup > Create a restore point or change settings. 1. Hack User Account Control in Windows Vista User Account Control (UAC) is the new operating system's most universally reviled feature. Sure, it helps protect you, but it also annoys you to the end. If UAC makes you bend around, you can turn it off. There are several ways to do this. One option is to select Control Panel > User Accounts and Family Safety > User Accounts, and then click Turn User Account Control on or off. Alternatively, you can run the System Configuration utility (a.k.a. msconfig) by typing msconfig in the command line or in the search box. When the tool is running, click the Tools tab, and then scroll down until you see the Disable UAC button. Highlight it, and then click Run, and then restart. To turn it back on, follow the same instructions and select Enable UAC. If you're a registry fan, you can also disable UAC by using Registry Editor. Run Registry Editor by typing regedit or command prompt in the Start Search box, and then pressing Enter. HKEY\_LOCAL\_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Policies\System\EnableLUA and give it a value of 0. You must restart the change for the change to take effect. UAC is also the culprit for another nagging Windows Vista resentment. When you run a command command from a command prompt, you are told that you do not have administrator privileges to run them, even if you are currently logged on as an administrator. This is because UAC requires you to run a command prompt as an administrator - called running an extended command prompt. Just logged in as an administrator is not good enough; however, you must run an extended command prompt. One way to do this is to cmd otsingukasti kohta Start Start Right-click the Command Prompt icon that appears at the top of the Start menu, and then select Run as administrator. But if you don't want to do this every time you run a command prompt, there's an easier way. For an extended prompt, you can create a desktop shortcut or pin an extended prompt to the Start menu. Create a shortcut on the desktop: 1. Right-click the desktop and select New > Shortcut. 2. In the Create Shortcut dialog box that appears, type cmd, and then click Next. 3. On the next screen, type a shortcut name - for example, an Extended Command Prompt. Then click finish. 4. Right-click the shortcut you just created and select Properties. 5. Select the Shortcut tab, and then click Advanced. Create an extended command prompt shortcut. Click to see a larger view. 6. Select the Run as administrator check box. Click OK, and then click OK again. Now, if you want to run an extended command prompt, just double-click the shortcut. If you want an extended command prompt to appear on the Start menu, drag it from the desktop to the Start button and place it where you want it. When you make a decision, what's exhausting for you- the rationalization of the cone or what does your gut tell you? I'll tell you what I believe in: in the real world, in practical research. And a lot of it. I want to know every facet of new product or technology before I judge it. I want to try it myself. Let it through different situations. Measure how it responds to different conditions and indicate how I and others respond to these things. It doesn't work so well with cookware, mobile phones or big-screen TVs because you can't have a real-world scenario in a showroom. But it works in cars pretty well if you're persistent about getting a decent test drive or two. And it especially works with computer software if you're a beta tester. My first copy of Windows Vista came to me at the end of 2003, and I can not even count on the number of builds I tested before the gold code arrived in late November. I have spent hundreds of hours testing Vista. In finally, although my decision comes to my gut. I'm doing objective and subjective research and waiting to see what my invisible, unknown jury says. This is

something like the Magic 8 Ball, except that unlike the 8 Ball, I've come to trust it. The only problem is that even after all that research in Vista, my inner 8 Ball keeps saying: Answer blurry, try again. How is that possible? What's wrong with Vista? At least 80% of the changes in Windows Vista are positive. Microsoft took extra time to smooth over some speed bumps in the noticeable pre-release builds of the operating system. You can't fault the software giant for lacking effort in the Vista development process. Graphics improvements, both hardware support and how the software uses this hardware, change the user interface scores and passed in a way, all of them are positive. One of the best advantages of Vista is that ergonomically, it is easier and just more satisfying - gut level - to use. On the other hand, something like Vista is truly innovative or compelling. With the exception of security (and we do not yet know whether Microsoft's security changes are sufficiently significant to change the Windows experience), there is no transformative, must-have-it feature in Vista.This is why computer software reviewers, though mostly positive, have struggled to put their fingers on exactly why they are positive. To use '90s vernacular, there is no killer feature; yet mostly most people prefer Vista over XP if they have had the opportunity to live on Vista for some time. Make no mistake, either: Windows Vista is successtful. In two years, it could be a roaring success. Even Windows ME - the most embarrassingly unin inspired version of Windows since Windows 2.0 - had relative financial success with Microsoft. Vista turns Windows ME into someone's Welcome World experiment. Why doesn't Vista pass my gut? Vista has become a version of Windows that I just can't get excited about. I was much more excited about Windows ME because I hated it. I don't even hate Vista. I'm really tired of it. If you're running Windows Vista, you'll need to start your web browser and install these four updates immediately. Many of the fixes we've been waiting for in Service Pack 1 can be found here, and they will greatly improve the performance and compatibility of the new OS. The first is KB938194. This Compatibility and Reliability update contains several improvements, including fixes to these issues: The screen may go blank when you try to upgrade a video driver. The computer stops responding, and you receive an error message when the display driver stopped responding and has recovered. The computer stops responding or restarts unexpectedly when you play video games or perform desktop tasks. The Diagnostic Policy Service (DPS) stops responding when the computer is under heavy load or when very little memory is available. This issue prevents the diagnostic from running. The screen goes blank after the external display device connected to your computer is turned off. Some graphics processors (GTOs) have stability problems. These issues may cause the GPU to stop responding (hang). Visual appearance problems occur when playing graphics-intensive games. You experience poor playback quality when you play HD DVD discs or Blu-ray discs on a large monitor. Applications that load Netcfgx .dll unexpectedly exit. Windows Calendar closes unexpectedly after you create a new appointment, create a new task, and then restart your computer. Internet connection sharing stops responding after you upgrade a computer that is running Microsoft Windows XP Vista, and then restart the computer. The printer spooler service stops unexpectedly. You receive the Stop 0x0000009F computer sleep mode error message when the point-to-Point Protocol (PPP) connection is active. Next, and perhaps more importantly, is update KB938979 for performance and reliability. Updates contain fixes to these issues: You experience a long delay when you try to exit the photos screen saver. A memory leak when you use a Windows Power screen saver. If User Account Control is disabled on your computer, you cannot successfully install the network printer. When you write data to an AVI file by using the AVIStreamWrite function, the AVI file header of the AVI file is corrupted. When you copy or move a large file, the estimated remaining time takes a long time to calculate and display. After your computer hibernate, it takes a long time to display the sign-in screen. When you synchronize an offline file with the server, the offline file is corrupted. When you edit an image file that uses raw image format, the image file experience data loss. This issue occurs if the TOOrpilt is canon EOS 1D and 1DS models. After the computer hibernate, the computer loses its default gateway address. Memory management performance occurs. This latter is quite vague for sure, but anything that improves Vista memory management is welcome. Microsoft actually released these updates earlier in August, and I've used them at home. They certainly work as advertised: Many operations in Explorer are snappier and the error estimated the time left in the file copies are gone. Feedback from other early adopters across the web shows that these two updates have disappeared with a lot of annoying minor errors, memory leaks, and problems. You can download them from knowledge base articles, but Microsoft has added them as critical updates in Windows Update this week. So if you haven't already run Windows Update, now is the time. These aren't the only two major corrections. Image-related updates that aren't available through Windows Update are also worth grabbing. Continued... Continued...
