The sound level decreases when getting further away from the microphone. For example, the sound level when playing next to the microphone is 20 dB, while it is 15 dB when playing 15 cm away. The microphones from which the voices are loudest in a vocalization are the best microphones for vocalizing. The best microphones for vocalizing is any microphone that is, A: The definition of loudest is pretty simple. loudest = loudest measured by some device, e.g. loudest vacuum cleaner in this house. Your definition of best doesn't make sense to me, you are basically asking "What is the best quality product?" The best, to me, would be the one which is loudest and is acoustically the most forgiving to the human ear. If that is your question, then any microphone will do the job just fine. 1. Field of the Invention The present invention relates to a method of manufacturing an LSI (semiconductor integrated circuit) and, more specifically, to a method of manufacturing a thin film transistor (hereinafter referred to as TFT) for use in a liquid crystal display device, a photosensor, or the like. The invention also relates to a semiconductor device using the TFT. 2. Description of the Related Art For display apparatus such as liquid crystal display apparatus and a display panel for an electrophotographic copier or a word processor, the use of a TFT as a switching element and a driving element has been recently being promoted. The TFT is manufactured generally by the steps of forming an electrode material thin film on an insulating substrate such as a glass substrate; heat-treating the thin film to form an amorphous semiconductor thin film (hereinafter referred to as amorphous film); and subjecting the amorphous film to a heat treatment for crystallization (hereinafter referred to as crystallizing heat treatment). It is known that the best crystal structure (polycrystal structure) for a semiconductor layer of a TFT (especially an a-Si:H) is a polycrystal with a tetragonal or cubic structure. Therefore, a heat treatment at a temperature of 600.degree. C. or lower is sufficient to obtain such a polycrystal. When an amorphous film is heat-treated to form a polycrystal, grain growth proceeds from an exposed portion of a nucleation source (a portion having 520db lae7
