Hypocretin/orexin neurons are restricted to the lateral hypothalamic area and are modulated by important factors such as the internal circadian clock as well as the external light–dark cycle. Here we investigate whether the endogenous circadian clock can also drive the activity of hypocretin/orexin neurons. Results We show that both the phase and amplitude of the circadian cycle are able to modulate the firing rate of hypocretin/orexin neurons in freely moving rats recorded by in vivo single-unit recordings. The influence of the circadian cycle on the activity of hypocretin/orexin neurons was independent of the SCN. The activity of hypocretin/orexin neurons was reduced during light phase and increased during dark phase. In contrast, the activity of hypocretin/orexin neurons did not show diurnal differences in SCN-lesioned rats and 520fdb1ae7
