machines . . . electric machines electrical machines,. Here is an image of a electrical machine. The armature windings, the face, and the insulation, are seen. The cover of the drawing is a picture of a squirrel cage induction motor. In the front of the drawing the windings can be seen. A motor is an electrical machine which converts electrical energy into mechanical energy. Although most motors can be described as electrical, the kinetic energy of the motion is produced by the mechanical work done on the rotor by the magnetic field of the motor. Because they are mechanical devices, most electric motors require electrical power to operate. Of all the motors, those which are most commonly seen are the three basic types of induction motors: the squirrel cage motor, the squirrel cage induction motor, and the induction motor. The most common types of electrical motors are induction motors. Because the speed of the motor is determined by the speed of the magnetic field, the speed of the motor is limited by the speed of the electrical power supply. The speed range of a motor depends upon the number of magnetic poles (n), the number of poles on the stator and the rotor. For each phase the stator, the rotor, and the field are in a right-angle relationship. We can see that in the back of the picture there are three of these motors. In a three-phase motor, all of
