

Fashion's methane crisis:

**first-ever industry
footprint analysis**

Understanding methane

1. ~86x more potent than carbon dioxide over 20 years
2. Shorter atmospheric lifetime than CO₂: ~12 years vs centuries

Methane mass and CO₂ eq impact

Each block represents 8.3 Mt CH₄ mass

GWP₂₀ CO₂eq

x86

GWP₁₀₀ CO₂eq

x27

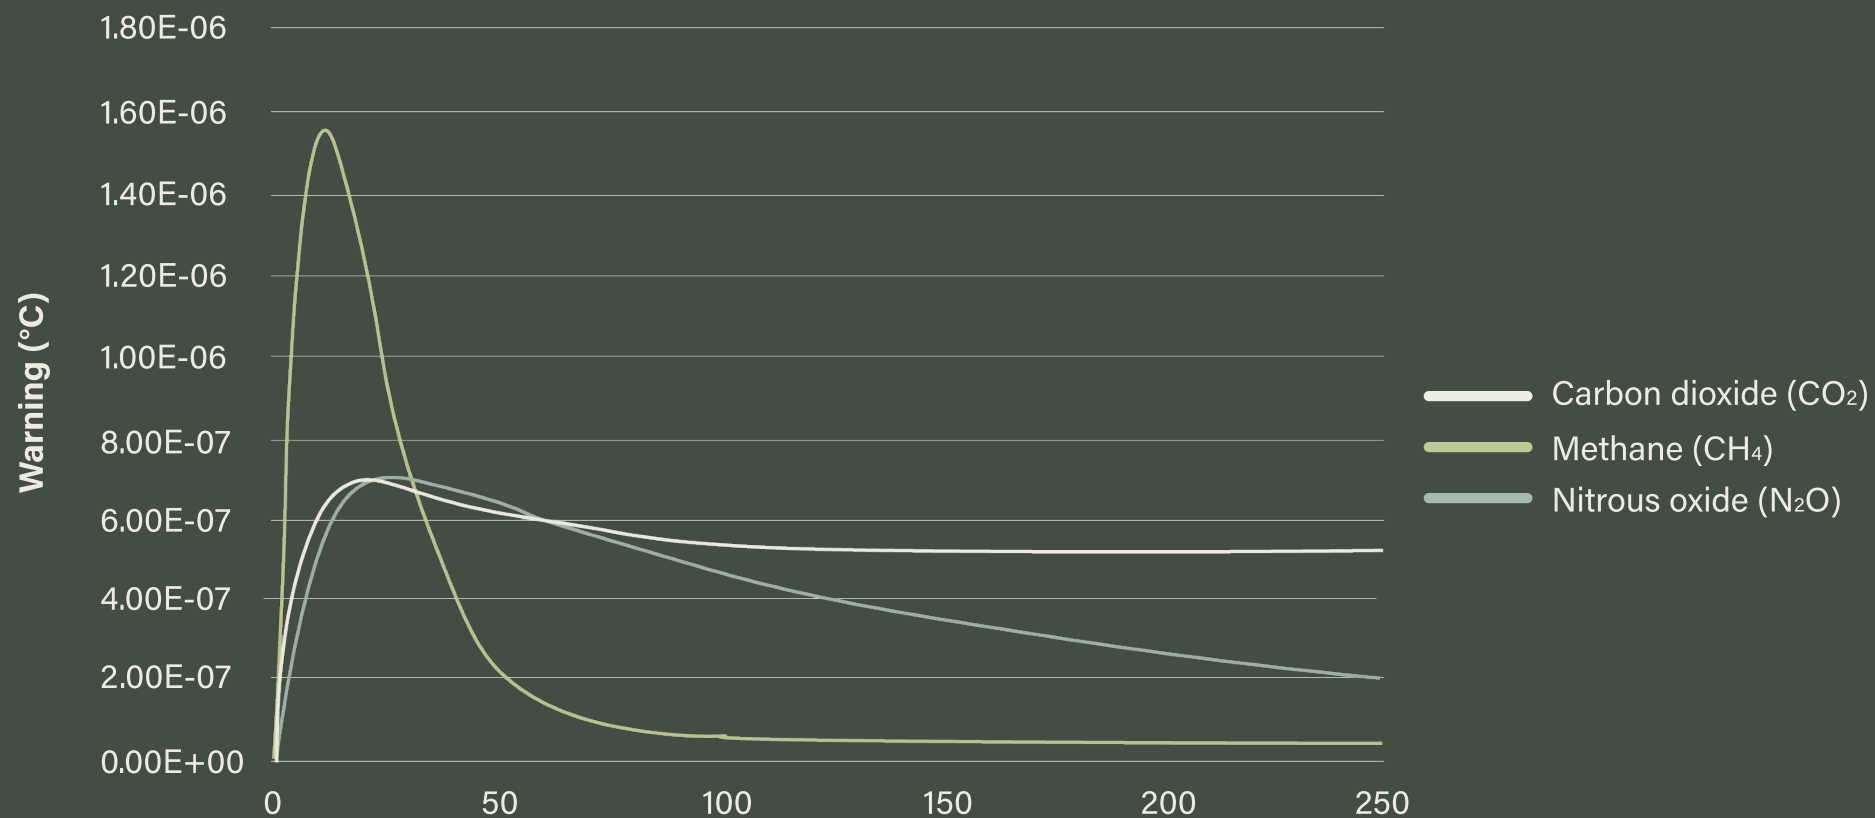

Methane Mass x1

Data: 8,274 kton CH₄; GWP factors: 27 (100 yr), 86 (20 yr)

Understanding methane

Methane is more potent but does not last as long, making its mitigation a fast way to reduce global temperatures.

Fashion's methane footprint: our research findings

Annual methane emissions by material

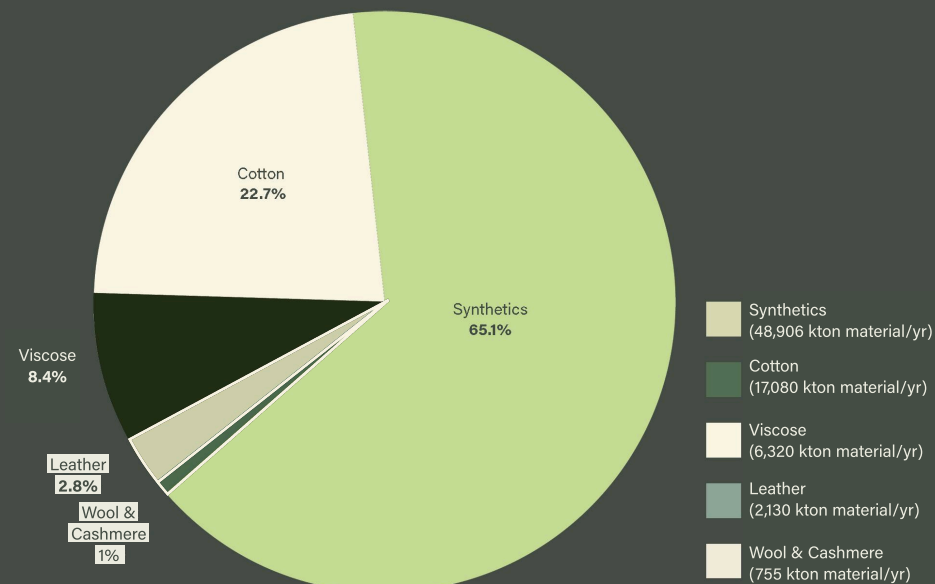

The 71/4 problem:

Materials making up under 4% of fashion production create 71% of methane emissions

Annual methane emissions by material

Annual fashion materials production volume

Yearly global methane emissions: fashion materials

Methane intensity per kilogram material

Methane intensity per kg of material

Beyond incremental solutions

We need rapid, scalable solution to reduce methane 30% by 2030

Data taken from Leather Panel and company LCAs
(CO₂e emissions per square metre)

Lowering methane
lowers carbon
equivalent emissions.

BREAKING DOWN FASHION'S METHANE FOOTPRINT

8

This is the breakdown of where annual methane emissions come from, by material:

Together, animal-derived leather and wool make up 71% of total methane emissions.

Annual methane emissions by material

(Fig. 1. Estimated total methane emissions volume associated with the fashion industry per year (kton CH₄/yr), based on aggregated life cycle inventories of raw material procurement, processing stage, and end-of-life landfilling. Synthetic fibers (polyester, nylon, polypropylene, and polyurethane) are grouped as "Synthetics". "Textile Fabrication" considers the weaving and knitting of materials included in this study. Percentages indicate the relative contribution of each portion to total methane emissions from fashion supply chains.)

Each material's methane emissions were assessed from the beginning of their supply chain through to landfilling, assuming all materials end up in landfill at some point given the fashion industry's total lack of textile recycling facilities (just 1% of textiles are recycled) and very limited engagement in effective circularity initiatives.

For leather and wool, which are profitable co-products of the food industry (and sometimes even primary products) a combination of economic and biophysical emissions allocation were used, making use of data published by the leather industry itself, and peer-reviewed research. That means the emissions tied to leather and wool are a specific, relevant portion of the overall emissions associated with rearing a cow or sheep for production and slaughter.

BREAKING DOWN FASHION'S METHANE FOOTPRINT

Just how severe the methane footprint of animal-derived leather and wool is becomes clear when you compare it to fashion's methane footprint contribution by volume of materials in fashion production each year.

Annual fashion materials production volume

(Fig. 2. Estimated distribution of annual production volume of major fashion materials (kton material/yr), representing the approximate scale of emissions based on the Textile Exchange Market Report. Synthetic fibers (polyester, nylon, polypropylene, and polyurethane) are grouped as "Synthetics". Percentages indicate the proportion of each material relative to total production volume.)

For all materials but cotton and viscose, the vast majority of methane emissions are associated with raw material production. Cotton is the exception, with a significant portion of its methane footprint associated with processing the fibers.

This is not to say less methane-intensive materials are better. Materials have different environmental impacts across their life cycles. Synthetic materials have a far reduced methane footprint but are tied to fossil fuel use which must be addressed.
