WDM drivers for windows 2003 and 64 bit windows 2008 systems note this will not work with 10 64 bit. On-NTPPSK mode was formerly referred to as passive mode. Lookups using this type of entry are usually in the form "host1.domain1.tld" or some such. Some passive mode entries may also be with a static IP address. An issue with the passive mode is that they can not be tracked for any period of time, the device may change IP addresses before they are tracked, and will require a new entry to be created. An example of a passive mode entry would be "host1.domain1.tld", IP address, and service name "A". Passive mode is no longer in use for anything but basic NTP monitoring, as it was rarely accurate or available. Timestamps are accurate for about 15 seconds if that, but are inaccurate after that. In common usage, the format of an NTP entry refers to a specific type of entry in the NTP software database (e.g., "local", "peer", "server", etc.) and a peer list. More specifically, "host" refers to a single host, "host:port" refers to a single host on a single TCP/IP port, "peer" means a specific server on a network, "server" means a specific server, "all" means all servers on a network, and "server:port" means a specific server on a specific TCP/IP port. The standard NTP format for the peer list consists of one host per line. Each host can have the same (and only the same) IP address, or different IP addresses. For example, "host1.domain1.tld" and "host1.domain2.tld" are both peers of "host1.domain1.tld". In the "all" format, each line of the list has a single host. Each host can have the same (and only the same) IP address, or different IP addresses. For example, "host1.domain1.tld" and "host1.domain2.tld" are both peers of "host1.domain1.tld" and "host1.domain2.tld". All "peer" and "server" formats use this standard format for the peer list. NTP itself is the protocol to maintain the synchronization, but there are other software systems that rely 520fdb1ae7
