HI 2270 printer

It's '80s, and this experimental fish consultant gets sent to see what's going on with a client who complains that the files are printed days and even weeks after they have been submitted. But not quite - just one or two pages at a time. Fish have a lot of things to check before giving serious consideration to the idea that there is a time gate hidden somewhere. It's netWare network on the shared axe. The server looks OK, and the fish see something in the queue. The printer looks fine too. But when the fish try to separate the BNC connector, it falls into his hand. Next, the wall socket opens — the co-axe is located outside the connector. Things need to look closely, and what the fish sees is that instead of kindness, even curls, there are marks that look like they're made by - pliers? So the fish demands rundown on the wires. Everything new, he was told, was done by an electrician who was there to do some other electrical wiring and asked him to put it in the shared axe mesh. Which he was happy to do, but he didn't have common axe tools, but he just cut and wrinkled with his electric pliers as he put in dozens of co-ax wall cranes and made some axe connector cables. The vast majority of those contacts only collapsed when touched. Fish uses a time range reflection scale to bounce the signal down the cables and see if there is any interruption etc. And it gets very strange readings and this leads to the discovery that the electrician has gone outside the building with two runs, then on the roof to different parts of the building - just to avoid all that pesky cable pull, you know, fish says. But where the cable wasn't long enough, the electrician just put the barrel connectors to paste into a new run of cable. Outside. On the surface with interior (i.e., not waterproof) conductors. The water was leaking into these connectors, of course, then draining to the lowest point of the cable. Because some of the wall cranes were leaking into the walls, there was mold as well. So is this weak network the gateway to time? It is a big part of it but the fish missed something in its first assessment of the situation: the main server does not print; Tasks are sent to the long-forgotten NetWare printing server in a closet. It will get jobs, then try to push them out of this water network, severely winding - and fail. But that would keep all the posts and try again - over and over again ... The fish company gets the job of re-finishing everything, replacing soaked cables when necessary (and not going on the surface). Someone else had to take care of the queue mold until real tales of IT life. Send them to Sharky in sharky@computerworld.com you can also subscribe to the Shark Daily Newsletter.
