Jana Eglit Researchers in Nova Scotia have found a unique species that appears to be from a whole new kingdom of life, separate from plants, animals, or almost everything else. The new discovery helps us learn more about life on Earth and how it evolved. In the Nova Scotia desert, biology graduate student Jana Eglit of Dalhousie University was hiking and decided to collect some mud samples. When she returned to the lab to analyze them, she discovered a strange microscopic creature she had only seen once: hemyamstyth. Gemimastigots have been studied since the 1800s, so it's not like Eglit has just discovered a new species. However, 19th century biologists had no access to modern DNA sequencing technology, so they were really flummoxed creatures. Until now, hemyistigoths have never sequenced their DNA. This new DNA sequence revealed a surprise: hemymastigotes are so far removed from all other forms of life that they probably deserve their own designation of the kingdom. Researchers found that these new creatures strayed from another life about a billion years ago, back when there were only a few multicellular life forms. So what does it mean that gemimogites are their own kingdom? At the highest level, all life is sorted into one of the three areas that are the category above the kingdom. Bacteria form one domain; their close relatives, archaea, form another. The latter area covers everything else, commonly referred to as eukaryotes. Gemystigoths are at least similar enough to animals and other life that they can fit in the area of eukaryotes. But beyond that, there is no other similarity between hemymastigotes and other life. All members of the eukaryote domain are organized into a handful of kingdoms, although there is still some debate about how many there are. The most widely accepted ones are: animals, plants, fungi, algae and protists, who basically just catch all the categories for things that don't fit into one of the other four groups. But gemitimeths are so strange and different that they can't fit into any of these categories - even one led by Dalhousie researchers, offering a new kingdom just for them. This decision cannot be taken lightly, of course, and still needs to be tested by other scientists. But it underlines how incredibly diverse life can be. You may be able to find more information about this and similar content on piano.io Fathers are not only important among humans, but also valuable in the animal world. The best fathers contribute to the safety, well-being and healthy development of their People. Worst fathers refuse, ignore, and even cannibalize cannibalism own young. Discover the best and worst fathers in the animal world. Penguins and seahorses are among the best fathers, while bears and lions are among the worst. PenguinsShorsesFrogs and Toad Bugs Grizzly BearsAssassin BugsSand Gobi FishLions Kim Westerskov / Getty Images Male Emperor Penguins are among the best fathers. When the female penguin lays an egg, she leaves it in the care of the pope, while going in search of food. Male penguins keep the egg safe from the icy cold elements of the Antarctic bioma, keeping them positioned between their legs and covered with their brood bag (feathered skin). Men may have to take care of eggs without eating themselves for as long as two months. If the egg hatches before the female returns, the male feeds the chicken and continues to protect it until the mom returns. Brandi Mueller/Getty Images Men's seahorses have taken fatherhood to a whole new level. They are actually the birth of their young. Men have a bag on the side of their body in which they fertilize the eggs laid by their female mate. A female seahorse can put thousands of eggs in a male bag. The male seahorse creates a favorable environment in the bag, which is optimal for the proper development of eggs. Dad takes care of the children until they are fully formed, which can take up to 45 days. The male then releases the tiny babies from the bag into the surrounding water environment. Kevin Schafer/Getty Images Most male frogs and toads play a vital role in the development of their young. Male phantasmal venomous frogs guard eggs laid by females after mating. As the eggs hatch, the resulting tadpoles will use their mouths to climb on their father's back. Male frog gives tadpoles a piggy-back ride to a nearby pond where they can continue to mature and develop. In other types of frogs, the male will protect tadpoles by holding them in his mouth. Male midwife toads care and protect a string of eggs laid by females by wrapping them around the hind legs. Men take care of eggs for a month or longer until they can find a safe body of water in which to deposit eggs. Jaki Good Photography/Getty Images Men of Giant Water Bugs ensure the safety of their young ones by eding them on their backs. After mating with the female, the female lays eggs (up to 150) on the back of the male. The eggs remain tightly attached to the male until they are ready to hatch. A male giant water bug carries eggs on their backs to make sure they are safe from predators, mold, parasites, and keep them fizzy. Even after the eggs hatch, the male continues to take care of his young for as long as two years. Paul Souders/Getty Images Male grizzly bears are among the worst animal fathers. Male grizzlies are lonely and spend most of their alone in the woods, except when it's time to mate. Female grizzly grizzly usually mate with more than one male during the mating season and cubs from one litter sometimes have different fathers. After the mating season, the male continues his solitary life and leaves the female responsible for the education of future cubs. In addition to being an absentee dad, male grizzlies sometimes kill and eat cubs, even their own. Thus, the mother grizzlies become fiercely protective of their cubs when the male is nearby and tends to avoid males in general while caring for the young. Paul Starosta/Getty Images Male Killer Mistakes actually protect their young after mating. They guard the eggs until they hatch. In the process of protecting the egg however, the male will eat some of the eggs around the perimeter of the egg grouping. This action is considered a protective mechanism that protects the eggs at the center of the brood from parasites. It also provides a man with nutrients as he should stop finding food while saving eggs. A male bug killer leaves him young once hatched. Young bug killers are left to fend for themselves as female bug killers die soon after laying their eggs. Reinhard Dirscherl/Getty Images Male sand gobi fish build nests on the seabed to attract mates. After mating, they are thoroughly usually eggs and hatching when the females are around. Males keep the nest clean and fan the eggs with fins to ensure the young have a better chance of survival. These animal fathers however tend to eat some of the eggs in their care. Eating larger eggs shortens the time that males have to guard their young as larger eggs take longer to hatch than smaller ones. Some men behave even worse when women are not around. They leave their nests unattended, and some even devour all the eggs. Photo by Tambaco Jaguar/Getty Images Male Lions fiercely defend their pride against dangers on the savannah such as hyenas and other male lions. They do not, however, participate much in the upbringing of their cubs. They spend most of their time sleeping while female lions hunt and teach the cubs the skills needed for survival. Male lions tend to hog food and females and cubs can starve at times when prey is scarce. Although male lions usually do not kill their own cubs, it is known to kill cubs from other males when they take on new pride. Relations between the United States of America and the United Kingdom of Great Britain and Northern Ireland (UK) are at the bean almost two hundred years ago, before the United States declared independence from Great Britain. Although several European powers explored and formed settlements in North America, the British soon controlled the most lucrative seaports on the Coast. These thirteen British colonies were the seedlings of what would become the United States. The English language, legal theory and lifestyle were the beginning of the beginning that has become a diverse, multi-ethnic, American culture. The term special relationship is used by Americans and Britons to describe the uniquely close relationship between the United States and the United Kingdom. The United States and the United Kingdom fought each other in the American Revolution and again in the War of 1812. During the Civil War, it was believed that the British sympathize with the southerners, but this did not lead to a military conflict. In World War I, the United States and Britain fought together, and in World War II, the United States joined the European part of the conflict to protect the United Kingdom and other European allies. Both countries were also strong allies during the Cold War and the first Gulf War. The United Kingdom was the only supreme world power to support the United States in the war in Iraq. U.S.-British relations were marked by close friendships and working alliances between senior leaders. These include links between Prime Minister Winston Churchill and President Franklin D. Roosevelt, Prime Minister Margaret Thatcher and President Ronald Reagan, as well as Prime Minister Tony Blair and President George W. Bush. The United States and the United Kingdom have huge trade and economic relations. Each country is one of each other's leading trading partners. On the diplomatic front, both are founding members of the United Nations, NATO, the World Trade Organization, the Group of 7 and other international bodies. The United States and the United Kingdom remain two of the five members of the United Nations Security Council, which have permanent seats and a veto over all Council actions. Thus, the diplomatic, economic and military bureaucracy of each country is constantly discussed and coordinated with its counterparts in another country.
