It is a process of creating a copy of all of a programs files and adding a new executable section to it with a new start address and a new command to execute. The program can then execute itself as usual. They are also known as polymorphic viruses, the file could be detected as a virus and by just running a virus scan, your operating system would be (temporarily) infected. Some viruses are dependent on the program they infect, if you change the program then they wont work. There are three different techniques to do this: The simple but slow approach of creating a copy of the code and inserting the new code into a section of the new program's file. The faster but more resource intensive approach of starting with a clean executable and using a hex editor to create a new section of code. The third approach is the easiest but not necessarily the fastest: it is an in-memory polymorphic virus. The in-memory approach generates an in-memory executable from the clean executable and replaces the executable in the process's memory with it. As this is an in-memory approach the change of executable will only be noticed by the particular program that the virus is attacking (as the in-memory executable is running as the same process). As most virus writers are not going to write a complete virus for every program out there, there will be a list of programs that they include. Virus writers usually have a list of targets in a spreadsheet. They are not limited to just Windows programs. Some programs for example, can be used to launch others, programs such as the Java Runtime Environment, Microsoft Visual Studio, or Groove Music. The most popular in the field of PC malware are the Backdoor.Win32.Zbot and Backdoor.Win32.Genesys. The following is a list of malicious programs that are similar to polymorphic viruses. 2. Brute-force programs are programs that randomly try input and output combinations on a program. Such programs are used for instance, to find the user name and password, so they can be used to gain unauthorized access to a computer. They are also used for dictionary attacks, which try out every possible combination of words to guess what the password might be. Examples of brute-force programs: 3. Blackhats are programs that are made to look like legitimate programs or Internet sites. These are mostly a form of social engineering. Blackhat software is 520fdb1ae7
